Point and geometric transformations, (chap 3 Birchfield) 2023  
Interpolation and warping (3.8 - 3.9)

# Arbitrary geometric transformations – Interpolation and Warping (3.8-3.9)

Three points from the topic:

1. How to interpolate in two dimensions?
2. Warping - think of a real world example
3. Types of transformations

From wikipedia

## (3.8) Interpolation

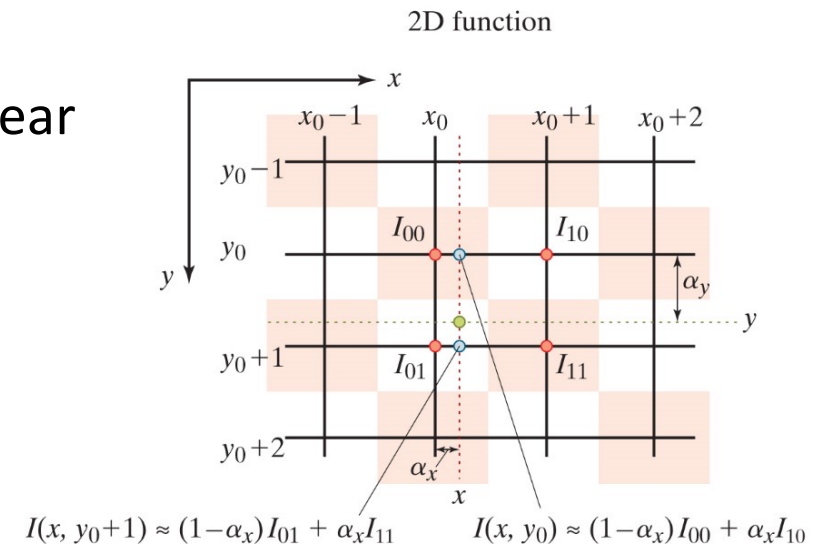

- **Nearest neighbor interpolation:** returns the gray level of the pixel nearest the coordinates:

$$\hat{I}(x, y) \equiv I(\min(\max(\text{ROUND}(x), 0, \text{width} - 1)), \min(\max(\text{ROUND}(y), 0, \text{height} - 1)))$$

- if bounds checking can be assumed:  $\hat{I}(x, y) \equiv I(\text{ROUND}(x), \text{ROUND}(y))$

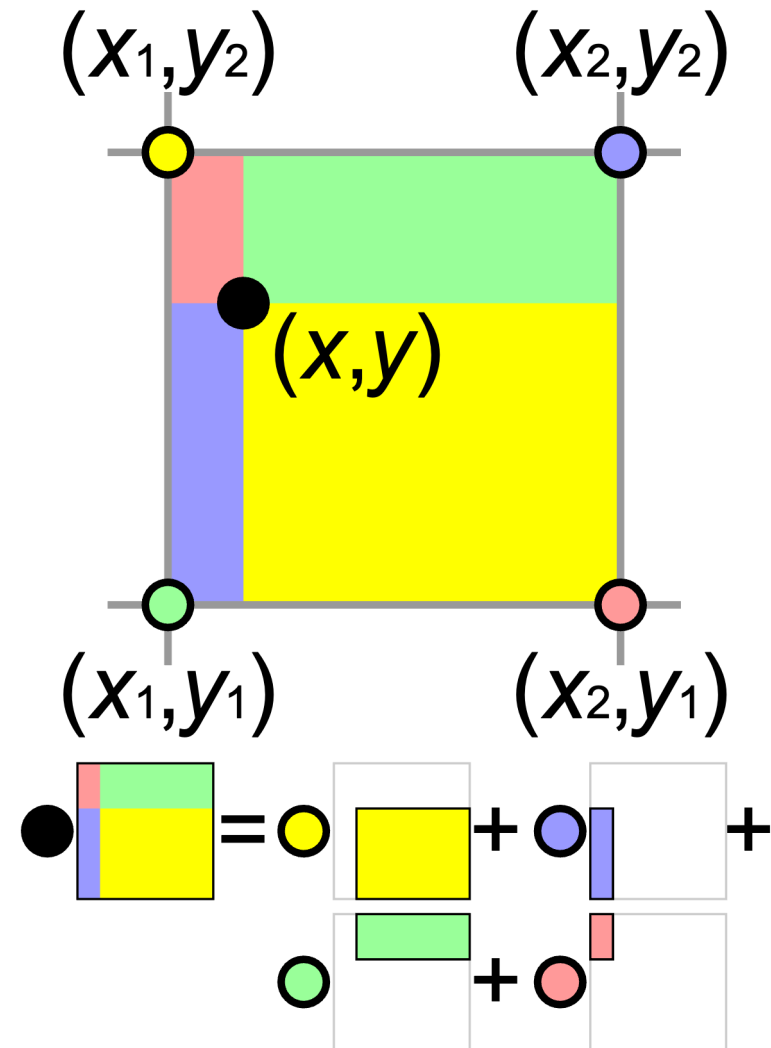

- **Bilinear interpolation:** a 2D extension of 1D linear interpolation. The interpolated value is the weighted average of the four nearby pixels:

$$\hat{I}(x, y) = \bar{\alpha}_x \bar{\alpha}_y I_{00} + \alpha_x \bar{\alpha}_y I_{10} + \bar{\alpha}_x \alpha_y I_{01} + \alpha_x \alpha_y I_{11}$$

# Bilinear Interpolation

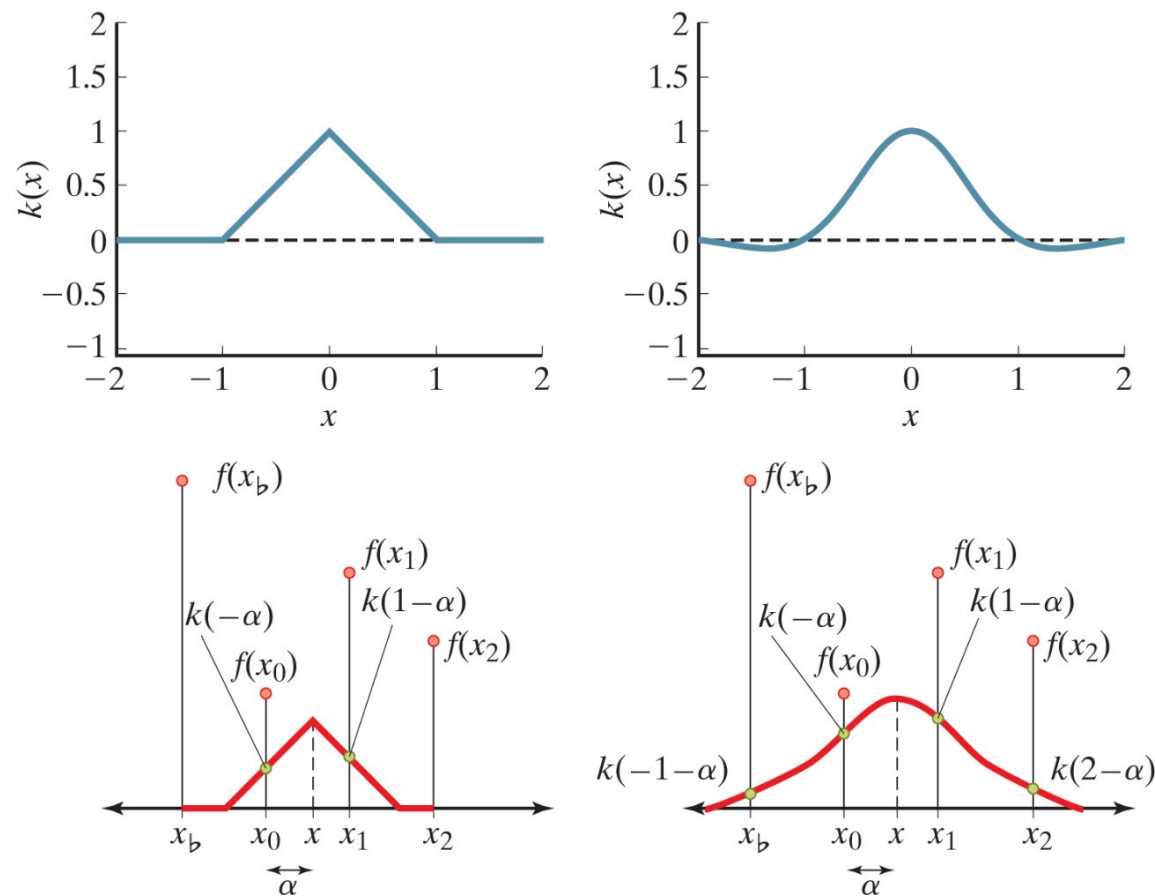

The product of the value at the desired point (black) and the entire area is equal to the sum of the products of the value at each corner and the partial area diagonally opposite the corner (corresponding colours).

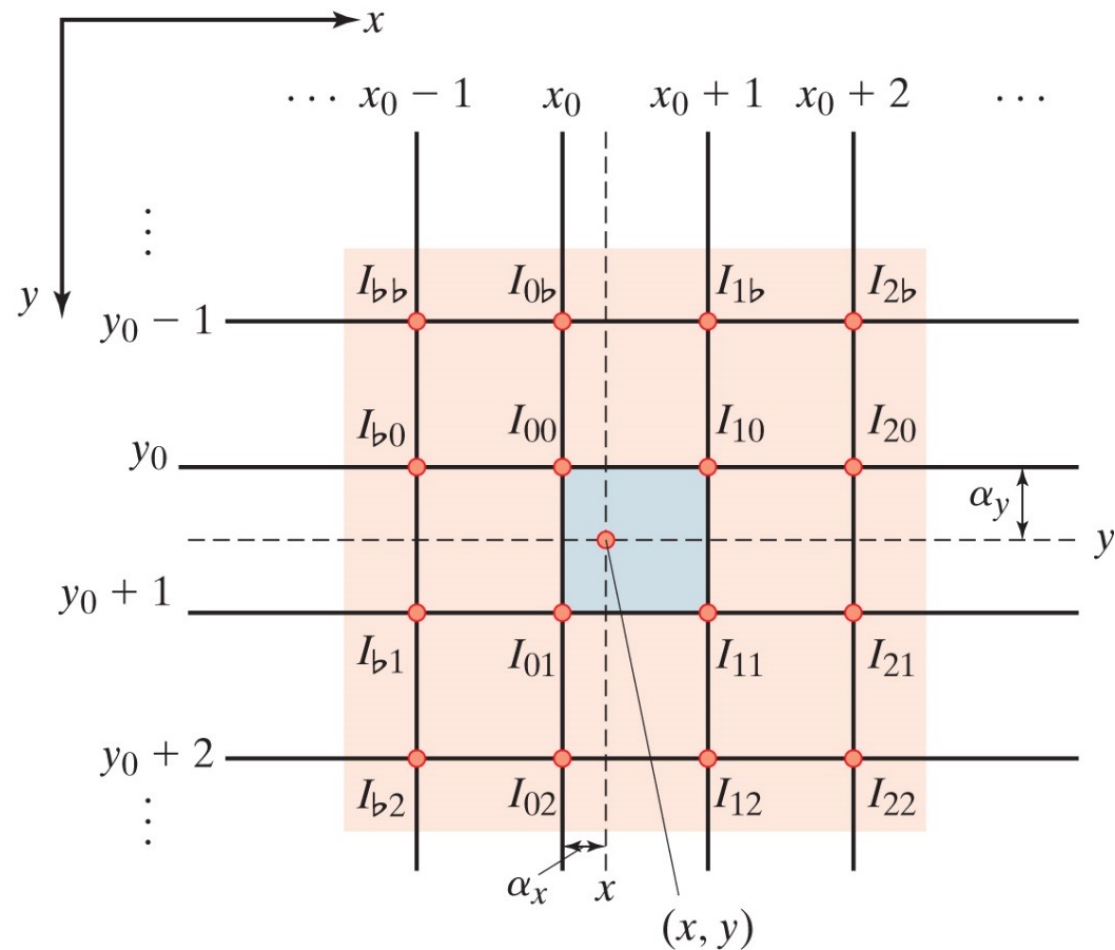

If the **derivatives** are known, or can be estimated, **cubic interpolations** can be used. More computationally demanding.

Interpolation can be visualized by using a kernel function:

**Figure 3.35** TOP: Linear (left) and cubic (right) 1D interpolation kernels. The dashed line indicates  $k(x) = 0$  to emphasize that the cubic interpolation kernel contains negative values. BOTTOM: Interpolation involves shifting the kernel so that it is centered at the desired position  $x$ , then the neighboring samples are combined using the weights from the kernel.

**Figure 3.36** Bicubic interpolation at a point  $(x, y)$  is a weighted average of the 16 nearby gray levels.

Less computationally demanding, and better cubic filters can be found: Key filters, Mitchell filter. Other interpolation kernels: Lanczos, based on sinc function. ( more details in the book)

## (3.9) Warping

- Consider arbitrary geometric transformations from real-valued coordinates  $(x, y)$  to real-valued coordinates  $(x', y')$ :

$$I'(x', y') = I(x, y)$$

- The **mapping function**  $f: \mathbb{R}^2 \rightarrow \mathbb{R}^2$  specifies the transformation, or **warping**, from the input coordinates to the output coordinates:

$$(x', y') = f(x, y)$$

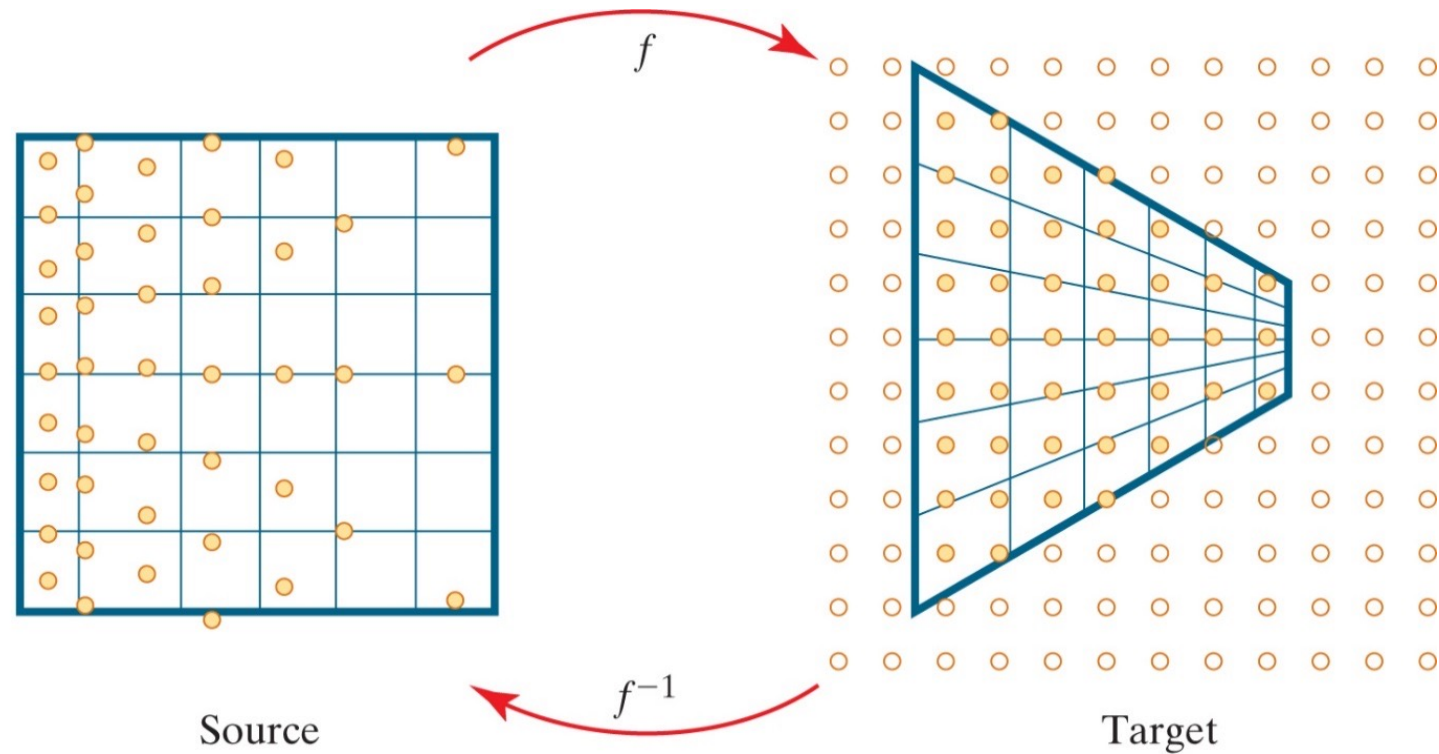

$$(x, y) = f^{-1}(x', y')$$

- Use the **invers transformation** to be sure to give each output pixel one and only one value.
- Interpolation** is used to find  $I(x,y)$  for real valued  $(x,y)$ .

**Figure 3.41**

A frontoparallel plane in the input is warped to a slanted plane in the output. The inverse transformation guarantees that every pixel in the output receives a value, whereas the forward transformation leads to some pixels not receiving values while others receive multiple values. Based on Burger and Burge: W. Burger and M. J. Burge. *Digital Image Processing: An Algorithmic Introduction Using Java*. Springer, 2008.

# Warping - Transformations

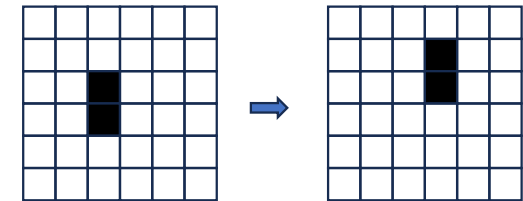

$(x', y')$  is output image coordinates and  $(x, y)$  input image coordinates:  $I'(x', y') = I(x, y)$

Translation:

$$x' = x + tx$$

$$y' = y + ty$$

$$\begin{bmatrix} x \\ y \end{bmatrix} = f^{-1}(x', y') = \begin{bmatrix} x' - tx \\ y' - ty \end{bmatrix}$$

$$tx = 1, ty = -1$$

Need an edge strategy. What do we do when  $x' - tx$  is outside the original image?  
Mirror, zeros, etc.

# Warping - Transformations

$(x',y')$  is output image coordinates and  $(x,y)$  input image coordinates:  $I'(x',y')=I(x,y)$

Rotation:

Clockwise by an angle  $\Theta$  (the origin is the upper left corner)

$$\begin{bmatrix} x' \\ y' \end{bmatrix} = \underbrace{\begin{bmatrix} \cos\theta & -\sin\theta \\ \sin\theta & \cos\theta \end{bmatrix}}_R \cdot \begin{bmatrix} x \\ y \end{bmatrix} = x' = Rx$$

Rotate around a point  $c$ :

$$\begin{bmatrix} x' \\ y' \end{bmatrix} = \begin{bmatrix} \cos\theta & -\sin\theta \\ \sin\theta & \cos\theta \end{bmatrix} \cdot \begin{bmatrix} x - cx \\ y - cy \end{bmatrix} + c$$

Properties of rotation matrices;

1.  $R^{-1} = R^T$
2. Norms of rows and columns = 1
3. Columns and rows are orthogonal to each other

# Warping - Transformations

- Translation and rotation can be combined into a single **Euclidean transformation**:

$$\mathbf{x}' = \mathbf{R}(\mathbf{x} - \mathbf{c}) + \mathbf{c} + \mathbf{t} = \mathbf{R}\mathbf{x} + \tilde{\mathbf{t}}$$

$$\begin{bmatrix} x' \\ y' \end{bmatrix} = \underbrace{\begin{bmatrix} \cos\theta & -\sin\theta \\ \sin\theta & \cos\theta \end{bmatrix}}_{\mathbf{R}} \begin{bmatrix} x \\ y \end{bmatrix} + \begin{bmatrix} \tilde{t}_x \\ \tilde{t}_y \end{bmatrix}$$

$$\tilde{\mathbf{t}} \equiv \begin{bmatrix} \tilde{t}_x & \tilde{t}_y \end{bmatrix}^T = -\mathbf{R}\mathbf{c} + \mathbf{c} + \mathbf{t}$$

Euclidean transformations preserves shape and scale of an object

- Can be written compactly and conveniently using **homogeneous coordinates**:

$$\begin{pmatrix} x' \\ y' \\ 1 \end{pmatrix} = \begin{pmatrix} \cos\theta & -\sin\theta & \tilde{t}_x \\ \sin\theta & \cos\theta & \tilde{t}_y \\ 0 & 0 & 1 \end{pmatrix} \cdot \begin{pmatrix} x \\ y \\ 1 \end{pmatrix}$$

# Warping - Transformations

- **Similarity transformations**: a superset of Euclidean transformations including translations, rotations, AND uniform scaling:

$$\begin{bmatrix} x' \\ y' \\ 1 \end{bmatrix} = \begin{bmatrix} k \cos \theta & -k \sin \theta & k\tilde{t}_x \\ k \sin \theta & k \cos \theta & k\tilde{t}_y \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} x \\ y \\ 1 \end{bmatrix}$$

Uniform scaling:  $x' = kx$ ,  $y' = ky$

Similarity transformations **preserves shape** of an object

# Affine transformations

$$\begin{bmatrix} x' \\ y' \end{bmatrix} = \begin{bmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{bmatrix} \begin{bmatrix} x \\ y \end{bmatrix} + \begin{bmatrix} a_{13} \\ a_{23} \end{bmatrix}$$

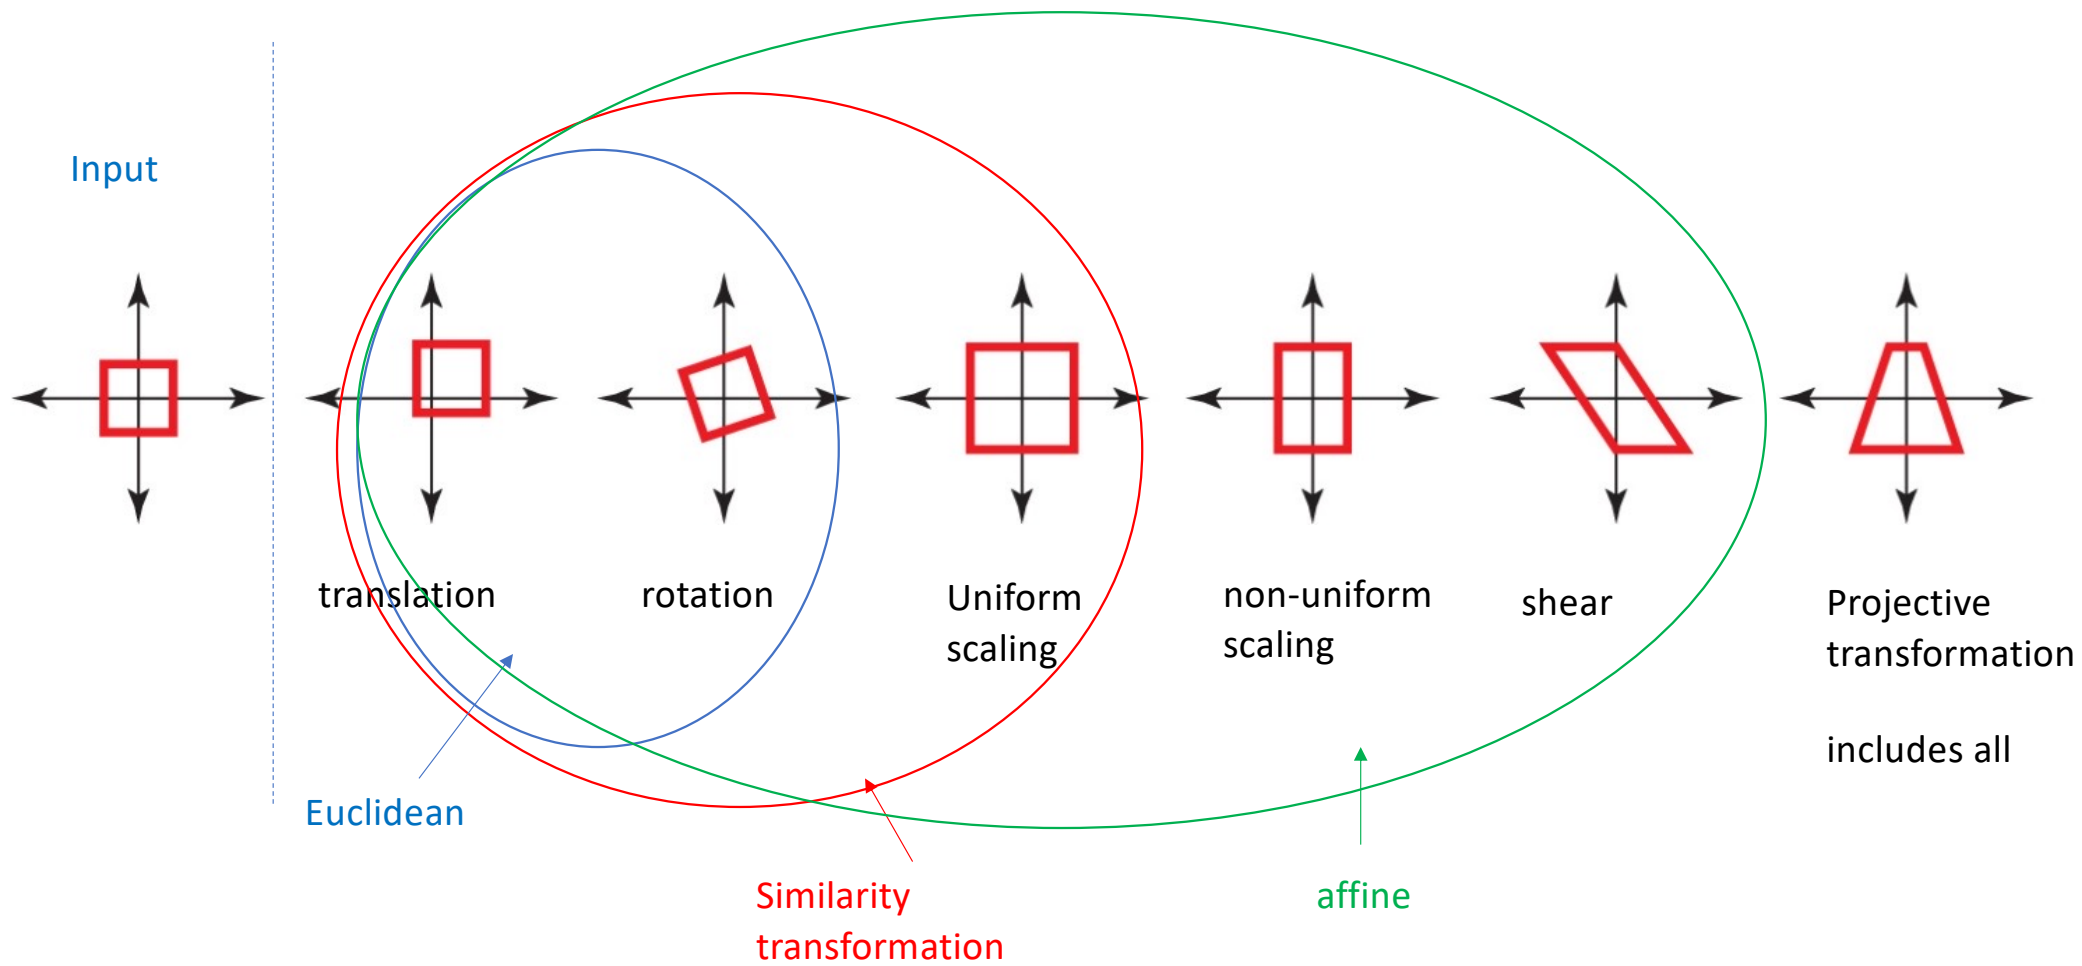

- **Affine transformations.** Any 2x2 invertible matrix. In homogeneous coordinates:

$$\begin{bmatrix} x' \\ y' \\ 1 \end{bmatrix} = \begin{bmatrix} a_{11} & a_{12} & a_{13} \\ a_{21} & a_{22} & a_{23} \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} x \\ y \\ 1 \end{bmatrix}$$

$$\begin{bmatrix} x \\ y \\ 1 \end{bmatrix} = \frac{1}{a_{11}a_{22} - a_{12}a_{21}} \begin{bmatrix} a_{22} & -a_{12} & a_{23}a_{12} - a_{22}a_{13} \\ -a_{21} & a_{11} & -a_{23}a_{11} + a_{21}a_{13} \\ 0 & 0 & a_{11}a_{22} - a_{12}a_{21} \end{bmatrix} \begin{bmatrix} x' \\ y' \\ 1 \end{bmatrix}$$

- Include: rotation, translation
  - Uniform scaling
  - Non-uniform scaling  $x' = ax$   $y' = by$
  - Shear  $x' = x + ay$ ,  $y' = y$

All affine transformations: Parallel lines in input -> parallel lines in output

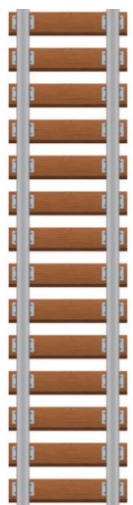

# Projective transformations

- **Projective Transformations.** Relax the constraint of the bottom row of the transformation matrix ( 3x3 invertable matrix, homography)

$$\begin{bmatrix} x' \\ y' \\ 1 \end{bmatrix} \propto \underbrace{\begin{bmatrix} h_{11} & h_{12} & h_{13} \\ h_{21} & h_{22} & h_{23} \\ h_{31} & h_{32} & h_{33} \end{bmatrix}}_{\mathbf{H}} \begin{bmatrix} x \\ y \\ 1 \end{bmatrix}$$

Includes all affine transformations

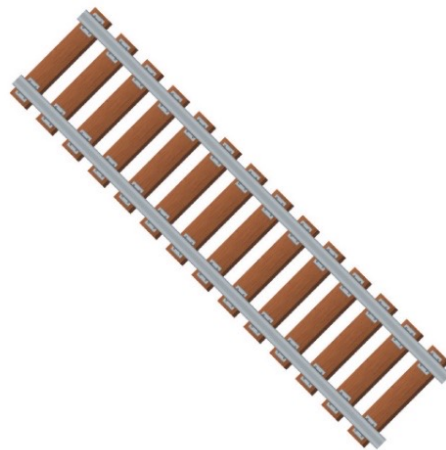

+ parallel lines in input -> intersecting lines in output

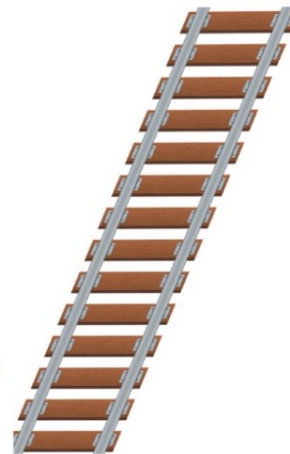

Image

Translation

Rotation

Affine

Projective

# Other Warping related operations

- **Image registration** – Sometimes it is desirable to align two input images. Simple to complex solutions depending on application
  - Medical images
  - Images of same scene, different locations

# Other Warping related operations

- **Morphing** – If two images are both registered and also dissolved into each other, we say that they are morphed.
  - morphing of a persons face onto another, snapchat filters etc
  - Continuous scene change in video
